Natural Language Queries using Large Language Models

Bachelor Thesis

Summer semester 2025

April 19, 2025

Mara Schulke – Matr-Nr. 20215853

Abstract

This thesis explores the integration of large language models (LLMs) into PostgreSQL database systems in order to make the database accessible via natural language instead of the postgres SQL dialect. The research focuses on implementation strategies, performance optimization, and practical applications of this concept.

1 Introduction

1.1 Problem Statement and Motivation

Database systems represent a backbone of modern computer science, allowing for rapid advancements whilst shielding us from the problem categories that come along with managing and querying large amounts of, usually structured, data efficiently. However, most Database Management Systems (DBMS) have traditionally required specialized knowledge, usually of the Structured Query Language (SQL), in order to become useable. Whilst this barrier may be perceived differently across diverse usergroups it represents a fundamental misalignment between end-user goals (e.g. analysts, researchers, domain experts etc.) and the underlying DBMS, thus often requiring software engineering efforts in order to reduce this friction.

This barrier is the reason entire classes of software projects exists (for example, admin / support panels), data analytics tools etc. which therefore introduce significant churn and delay between the implementation of a database system and reaching the desired end user impact. Often these projects span multiple years, require costly staffing and yield little to no novel technical value.

Emerging technologies such as Large Language Models (LLMs) have proven themselves as a sensible tool for bridging fuzzy user provided input into discrete, machine readable formats. Prominent models in this field have demonstrated outstanding capabilities that enable computer scientists to tackle new problem classes, that used to be challenging / yielded unsatisfying results with discrete programming approaches.

This thesis is exploring ways to overcome the above outlined barrier using natural language queries, so that domain experts, business owners, support staff etc. are able to seamlessly interact with their data, essentially eliminating the requirement of learning SQL (and its pitfalls). By translating natural language to SQL using Large Language Models this translation becomes very robust (e.g. against different kinds of phrasing) and enables novel applications in how businesses, researchers and professionals interact with their data — it represents a fundamental shift (ie. moving away from SQL) towards a more inclusive and data driven world.

1.2 Objectives of the Thesis

This thesis aims to address the aforementioned challenges when it comes to database accessibility. The following objectives are the core research area of this thesis:

1. Develop a database extension that can translate natural language queries into semantically accurate SQL queries using Large Language Models.
2. To evaluate the effectiveness and feasibility of different Models aswell as prompt engineering techniques in order to improve the performance of the system.
3. Identify and address issues when it comes to handling ambiguous, complex and domain specific user input.
4. Benchmark the performance of the implementation against common natural language to SQL (NL2SQL) benchmarks.
5. Identify potential use cases for real world scenarios that could deliver a noticable upsides to users.
6. Analyze the shortcomings and limitations of this approach and propose potential solutions to overcome them.

1.3 Research Questions

RQ1 — Are natural language database interfaces feasible for real world application?

The primary research questions when it comes to natural language database interfaces evolve around their semantic accuracy and reliability, therefore questioning their feasibility for real world usage. LLMs have notoriously been known for their ability to hallucinate / produce false, but promising outputs. This behaviour can be especially dangerous when opting for data driven decisions that rely on false data due to a mistranslation from natural language to SQL. LLMs could cause hard to understand and debug behaviour, like false computation of distributions when the intermediate format is not being shown to the user. This thesis tries to determine whether such hallucinations could be reasonably prevented and whether the associated performance and hardware requirements are suitable for a real world deployment, outside of research situations.

Specifically the two big underlying questions are:

1. Is the semantic accuracy of natural language database interfaces high enough to yield a noticable benefit to users?
2. Is it possible to run such an interface on reasonable, mass available hardware (e.g. excluding high end research GPUs).

RQ2 — Are there effective approaches against ambiguity in natural language input?

To provide semantically correct results ambiguity in the user-provided natural language queries must be adequately addressed. This thesis investigates various approaches to ambiguity management and resolution. Natural language queries can demonstrate ambiguity even at low levels of complexity — e.g. there are two different types of "sales" in a database schema, and the user asks to retireve "all sales".

Such situations present the second major challenge associated with the practical implementation of natural language database interfaces. The success of this concept will significantly depend on whether suitable designs and mitigation techniques can be implemented without creating problems with regards to the aforementioned performance and hardware requirements. The research focus lies on both preventative measures through optimized pre-processing stages and prompt engineering techniques as well as reactive strategies that post process LLM output, either on the basis of further user input or context inference.

RQ3 — What are effective approaches for increasing semantic accuracy of queries?

In order to enhance the semantic accuracy a series of improvements may be applied to the pipeline. Potential optimizations include supplying (parts of) the schema during LLM prompting, implementation of interactive contextual reasoning through a conversational interface which would allow for user refinement, the implementation of a robust SQL parsing and validation mechanism and a hybrid approach partly relying on tradition NLP preprocessing techniques. This research will quantify semantic accuracy using popular NL2SQL benchmarks and empirically evaluate the impact each approach has on the benchmark performance. Furthermore this research will take a look at the optimal combination of the aforementioned solutions in order to develop a system that strikes the right balance between accuracy and performance.

1.4 Methodological Approach

This thesis is following a research and development methodology in order to implement a natural language interface for databases, in particular postgres is used.

1. **Literature Review** — An analysis of the existing research in the fields of natural language interfaces (NLI) for databases, GPU integration for acceleration of database operations, and LLM/AI Model integration within database systems. This phase establishes the theoretical foundation for this research and identifies current state-of-the-art approaches, their benefits and shortcomings.
2. **System Design** — Design of a system architecture that can utilize GPU acceleration for LLM integration from within postgres. The primary goals of the system design phase are to arrive at an architecture that yields low latency natural language processing, schema-aware SQL query generation, ambiguity detection and resolution whilst maintaining a high semantic accuracy.
3. **Implementation** — The implementation of a PostgreSQL extension according to the above system design that relies on `rust` and `pgrx`. This extension will provide a GPU accelerated framework for executing LLMs, implement a natural language to query generation pipeline that relies on the SQL schema and create database functions and operators for both query generation and execution.
4. **Evaluation and Benchmarking** — An assesment framework and benchmark that introspects the implementations performance in multiple dimensions. Namely the most relevant dimensions for this thesis are:
 - (a) Semantic Accuracy — Measuring the overall accuracy of results delivered for a given natural language input.
 - (b) Performance Metric —
